AUTHOR: Bogomol'nyy, L. B., Eng. Mat.

TITLE: Conclusions Suggested by Actuality (Vyyvody, podskazannyye zhizn'yu)

PERIODICAL: Vestnik Vozdushnogo Flota, 1957, Nr 5, pp. 69-71 (USSR)

ABSTRACT: A discussion of the standard of work performed by the airplane armament servicing personnel. The writing of this article was prompted by the articles published in the Vestnik Vozdushnogo Flota, Nr 10, 1956, by Eng. Lt Col B. S. Vinnik and in Nr 6, 1955, by Eng. Lt Col. V. Malygin. The author states: The time allotted for the preparation of fighter armament is ample; it should not be cut at the expense of quality. The scope of work of airplane armament specialists is already big; it should not be made larger by adding unreasonable operations. The dummy cartridges were proved able to cause a gun to fail firing; their use was discontinued and should not be introduced again. The use of safety devices during the taxiing of the airplane returning from firing exercises is not efficient. It is risky to tow an airplane returning from firing exercises without previously inspecting its armament in the safety

Card 1/3

Conclusions Suggested by Actuality (Cont.)

86-5-13/24

Card 2/3

zone. When work on armament is in progress, no other operations should be performed in the cabin. The best time to prepare the bombing and rocket-firing armament is after the completion of other jobs. From the point of view of safety, it is useless to try to use more than one blank cartridge to ensure safety of a weapon on the ground. When the safety zone inspection and unloading of cannons, on airplanes returning from firing exercises are properly organized, there will be no delay of the next flight (one diagram). To prevent personnel from moving between the nose of the airplane and the flag, a line with two pennants attached should be stretched between the flag and the nose wheel. The bomb suspension rods should be long enough to facilitate the lifting of the bombs; the rods should be so threaded at both ends as to enable fitting them in eyes of different diameters (a two-view drawing is given.) The cannon barrels become excessively copper fouled after 80 to 100 rounds. Copper is removed with

86-5-13/24

Conclusions Suggested by Actuality (Cont.)

metal brushes. There is an urgent need for a copper removal device, preferably incorporated in the structure of the projectile itself. In the author's unit, the tools used for work on airplanes are kept in a box painted red inside and with recesses, each shaped to receive a tool. This enables one to ascertain at a glance whether all the tools are in the box. It is necessary to determine the maximum number of airplanes which can and should be serviced by an individual armament specialist. In order to raise the responsibility of the specialist, it is advisable to direct that the airplane armament specialist who prepares the armament for flight remain on duty during the full current flying day. Three figures.

TITLE: Study of the relative reactivity of 1,3-butadiene, 1-butene, and 2-butene in the cationic polymerization process

SOURCE: AN SSSR. Doklady, v. 159, no. 5, 1964, 1069-1071

TOPIC TAGS: copolymerization, butene, 1,3-butadiene, cationic polymerization

ABSTRACT: In recent years interest has been directed toward the relative reactivity of monomers in ionic and coordination-ionic polymerization processes. Of these the least known are the relative activities of monomers in cationic polymerization. Generally the reactivity of monomers is determined from the values of copolymerization constants. In this work copolymerization was investigated in 1,3-butadiene with 1-butene and 2-butene using C¹⁴ labeled butadiene. This produced more reliable data on the composition of the produced copolymers. Polymerization was conducted in ethyl chloride and toluene solutions. The concentra-

tion of monomers comprised 20 mole % and the concentration of $\text{AlC}_2\text{H}_5\text{Cl}_2\text{-H}_2\text{O}$ catalyst was 0.1 mole % relative to the monomer. In some experiments $\text{AlC}_2\text{H}_5\text{Cl}_2\text{-HCl}$ was used as a catalyst. The obtained results may be used for the elucidation of the nature of some secondary reactions which take place during cationic homopolymerization of dienes. Orig. art. has: 2 figures

pp. 731-733 (USSR)

ABSTRACT

The production of polymers from aliphatic compounds of the ethylene series on the basis of polymerization by free radicals is only possible for the first representative of this series, namely ethylene. The interaction of the free radicals with the ethylene homologues leads to the formation of low-molecular products due to the rupture reactions in the first stages of the process. Ziegler and his collaborators used the reaction between organo-aluminum compounds and titanium tetrachloride for initiating the ethylene polymerization. Further investigations in this field furnished the possibilities of initiating the olefin polymerization under formation

CARD 1 / 4

The Use of Catalysts based on Magnesium Halogen Alkyls and Titanium Tetrachloride in the Production of Amorphous and Crystalline Polymers from α -Olefins and Dienes

of homogeneously built (isotactic) polymers. Later on organo-aluminum compounds could be replaced by other organometallic derivatives, especially by sodium and lithium compounds. The mechanism of these reactions can for the time being not be considered as established. The reaction between the components of the Ziegler reaction has an oxidizing-reducing character and leads to the formation of titanium derivatives of low valence degrees. Ethane and ethylene develop as by-products in the case of triethylaluminum. Kondyrev and Fomina proved that the reaction between magnesium halogen alkyls and the salts of various metals (Fe, Cu, Co, Ni, Cr, Mo) leads to the formation of:

- a) equivalent quantities of a saturated and an unsaturated hydrocarbon which correspond to the alkyl of the organo-magnesium compound, and
- b) of reduced forms of heavy metals. The effectiveness of the system R - MgHal - $TiCl_4$ in the initiation of the polymerization was proved by the authors in the case of ethylene, propylene, styrene and isoprene. The former polymerizes at once without pressure or heating from out-

seide. The thus obtained polyethylene possesses $\eta = 2,55$ melting point $130 - 138^{\circ}\text{C}$, ultimate strength 335 kg/cm^2 and relative extension 730 %. These indices are analogous to those of polyethylene which is obtained by means of the ordinary Ziegler catalyst. Of great interest are data which were obtained by the authors from the polymerization of propylene. It was proved by the authors that on this occasion in the presence of magnesium chloroethyl and tetrachlorotitanium about the same quantities of an amorphous and a crystalline (isotactic) polymer-form develop. At the same time a fraction was isolated which is insoluble in boiling hexane and whose crystallizability was spectroscopically and X-ray structurally proved. In the case of the polymerization of isoprene various polymer forms were also isolated. The simultaneous production of cis-1,4-polyisoprene and trans-1,4-polyisoprene or of the amorphous and the isotactic polyisoprene directly prove that in the system coexist various catalytic

TITLE:

Reactions of the Triazenes With Dienols and Acids in Anhydrous Hydrocarbon Media (Reaktsii triazenov s diyenolami i kislotami v uglevodorodnykh bezvodnykh sredakh)

PERIODICAL:

Izvestiya Akademii nauk SSSR. Otdeleniye khimicheskikh nauk,
1958, Nr 9, pp 1094 - 1098 (USSR)

ABSTRACT:

It has already been found that the decomposition of aliphatic-aromatic triazenes in **anhydrous** media is accelerated by the catalytic effect of dienols and acids or acid-containing substances. The decomposition of triazenes can also be definitely accelerated in **anhydrous** hydrocarbon media in the presence of acids. This reaction is not a catalytic one, since esters form during the reaction (Refs 2,3). The authors were interested in the application of this reaction to the quantitative determination of carboxyl groups in organic compounds. They considered the investigation of the reaction between the triazenes and dienols in **anhydrous** media of still greater importance because of the possible use of this reaction

Card 1/2

Reactions of the Triazenes With Dienols and Acids in
Anhydrous Hydrocarbon Media SOV/62-58-9-12/26

in the alkylation or arylation of dienol groups. It was found that in **anhydrous** hydrocarbon media dioxymaleic acid and its diethyl ester and ascorbic acid accelerate the decomposition of the triazenes. The reaction is accompanied by the formation of nitrogen and the alkylation (or arylation) of the carboxyl and dienol groups. The authors found that the decomposition reaction of triazenes under the effect of acids can be used for the volumetric quantitative determination of carboxyl groups (especially in polymers) in **anhydrous** hydrocarbon media. There are 2 figures, 3 tables, and 8 references, 4 of which are Soviet.

TITLE: Use of the reaction of organodilithium compounds with metal halides for the synthesis of polymers with a conjugate system of double bonds

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Otdeleniye khimicheskikh nauk, no. 10, 1961, 1912

TEXT: It is known that the reaction of phenyl-magnesium halides with salts of metals of variable valency yields almost quantitative amounts of diphenyl (Ref. 1: see below): $C_6H_5MgI + Me^{n+1} \rightarrow C_6H_5 - C_6H_5 + Me^n$. It was shown that reactions of this type do not follow the radical mechanism (Ref. 2: Wang Fo-sung, B. A. Dolgoplosk, B. L. Yerusalimskiy, Izv. AN SSSR, Otd. khim. n., 1960, 469). In this connection, the above reaction proved suitable for the preparation of polymers from the corresponding bifunctional organometallic compounds. Publications show that oligophenylenes can be synthesized by reaction of orthodilithium benzene with heavy-metal halides

Card 1/3 X

20279

S/062/61/000/010/016/018

Use of the reaction of organodilithium... B106/B101

(Ref. 3: G. Wittig, F. Bickelhaupt, Chem. Ber. 91, 883 (1958)). The present authors obtained polymers with a condensed system of double bonds by reaction of p-dilithium benzene, p-dilithium diphenyl, and dilithium tetraphenyl butadiene-1,3 with titanium, vanadium, and cobalt halides. The first two monomers were synthesized by reaction of equimolecular amounts of a suspension of the corresponding dilithium derivatives in diethyl ether, hexane, or benzene with titanium tetrachloride or vanadium oxychloride at 20°C. The polymers are thus obtained in the form of dark-yellow or brown powders partly soluble in chloroform and benzene. The yields are 60 - 70%. Below 450°C, the polyphenylenes obtained are infusible, and contain a crystalline fraction, as shown by X-ray structural analysis. Reaction of dilithium tetraphenyl butadiene-1,3 with arsenic, antimony, and tin halides gives the corresponding heteroderivatives of tetraphenyl cyclopentadiene (Ref. 4: see below). It is shown that the use of titanium tetrachloride, vanadium tetrachloride, vanadium oxychloride, and cobalt chloride yields polydiphenyl acetylene (yield of up to 70%) of limited solubility in chloroform. On reaction with vanadium oxychloride, the soluble fraction is orange-colored, crystalline, and melts at 220 - 240°C. The mean molecular weight as determined with the aid of thermistors is

AUTHOR: Bogomolov, A. I., Engineer

TITLE: The Connection of a Boiler Tube Nest With the Housing of a Water Heater (Soyedineniye trubnogo puchka s korpusom vodopodogrevatelya)

PERIODICAL: Energetik, 1959, Nr 4, pp 12 - 13 (USSR)

ABSTRACT: The boiler tube nest of the water-water heaters of type Teploset' Mosenergo are fastened by two flanges to the housing, whereby one of the latter is screwed to the tube strainer. These flanges facilitate the removal of the boiler tube nest from the housing. The screw flange has several essential disadvantages: it does not provide a tight sealing of the connection, since the gaskets are frequently damaged; a considerable force is required for screwing and unscrewing; the tube strainer is deformed, since pins are inserted into its holes for screwing or unscrewing of the flange; etc. For these reasons, the boilers were rarely cleaned. A new type of flange (shown in Figure 1), used in the main building of the

2142. PETROLEUM LIKE LIQUID FROM TKIBULSK COAL DEPOSIT.
Dobryanskii AF and Bogomolov, AI (Zhur. Priklad. Khim. (J. Appl. Chem.), 1949, vol. 22, 639-643; abstr. in chem. abstr., 1949, vol. 43, 8122). A sample of the petroleum like fluid was analyzed by distillation (b. 134-550 with 35% residue) and examination of physical constants of the fractions. The product contains but 8-10% aromatics, 22% solid paraffins, has high melting points in all fractions (57 to 109°) and optical activity which rises with bp to 8-8.8° in the highest fractions probably due to derivatives of fichtelite.

Catalytic effect of geological formations on the composition of petroleum. A. P. Dobryanskii, A. I. Bogomolov, and I. V. Sibilyar. *Zhur. Priklad. Khim.* (J. Applied Chem.) 22, 1124-32 (1949).—Heating of wide fractions of cylinder oil with bentonite-glass ring packing in a Cu vessel at 250° 70 hrs. results in significant decyclization, as shown by the distn. curves, and characterized by lowering of the av. mol. wt. with simplification of chem. structure. The reactions which involve H transfer can be correlated with similar effects in nature, as shown by high content of paraffin fractions in petroleum from sources showing longer and most intensive oil formation. 2354. TRANSFORMATION OF HIGH-MELTING CERESINE OVER CLAYS. Borodolov, A.I., and Smirnova, A.I. (Zh. prikl. khim. [J. appl. Chem., U.S.S.R.], 1954, v.27, 673-677) abstr. In Chem. Abstr., 1954, vol. 48, 12356. Ceresine (melting 90°, d_{40}° 0.7854, n_D^{20} 1.4350) is unaltered by heating to 300. In the presence of activated clay it breaks down to give lower-boiling iso-paraffins and a residual ceresine that is enriched with normal hydrocarbons. Such enrichment is aided also by the loss of side chains. The liquid products are mainly saturated and consist of nearly equal amounts of paraffins and aromatic hydrocarbons, with but traces of naphthenes. The cracking process with clay gives results similar to those obtained with aluminum chloride.

/Primary bituminous substances in the sequence of transformation of organic residues into petroleum. A. I.

Borodolsky, Zhur. Priklad. Khim., 27, 1012-16 (1954).—

Examination of numerous samples of bituminous matter from various sections of U.S.S.R., with respect to the ratios of oils to asphaltenes and tars and the ratios of acidic to neutral tars, led to the following conclusions: The acidic nature of bitumen originates in organic silt. As the deposits slowly sink to deeper and hotter regions of the crust under reducing conditions, the acidic materials are partly converted to hydrocarbons which are distributed by diffusion. In the process of forming a petroleum deposit, the lighter, neutral fractions of bitumen are pressed out into "selective areas" of porous mineral structures, while the acidic components are retained because of their adsorptive power.

Abs Jour : Ref Zhur - Khimiya, No 1, 1958, 2531

Paraffinic structures in the AH of the heavy residues amount to 40%. The total number of rings in the molecules of AH increases from 1.5, in the case of the kerosene fractions, to 3.2 in the case of the heavy oil fractions. The AH of kerosene and oil fractions, of the investigated petroleum varieties, consist essentially of mixed forms, in which are present, in varying amounts, aromatic as well as naphthenic rings. AH found in fractions of the same boiling range, of paraffinic and paraffin-free tarry petroleum varieties, are of the same type and the difference consists only in their quantitative content in the petroleum. Groupwise composition of methane-naphthenic fractions shows more considerable fluctuations and is sharply distinct in petroleum of different type. The authors assert that formation of AH, in the case of all petroleum

Collected Papers (Cont.)

SOV/1960

chemistry. The work is divided into two parts, the first of which consists of 12 articles dealing with the development of theoretical problems in petroleum chemistry. The second part reviews problems connected with the study of organic and mineral crudes. In Part I, A. F. Dobryanskiy posits the low temperature origin of petroleum and rejects the popular claim concerning high temperature origin. The joint work of A. F. Dobryanskiy, P. F. Andreyev, and A. I. Bogomolov directs attention to the uniform phenomena in the composition of crudes that result from spontaneous changes in their substances through geological periods and which occur in full conformance with the basic laws of nature. The article supplements the basic principles developed by A. F. Dobryanskiy ten years ago in his well-known work, "Geokhimiya nefti" (Geochemistry of Petroleum). P. A. Demenkova, L. N. Zakharenkova, and A. F. Kurbatskaya report on the correlation of some microcomponents in the composition of crudes. Their extensive research combined with existing information permits them to draw interesting basic conclusions bearing directly on the origin of crude. Part II contains articles on new chemical, physical, and geochemical studies conducted at VNIGRI in recent years. Among these A. I. Bogomolov and K. I. Panina report on the particular characteristics of the aromatic hydrocarbon structure, which may prove useful for future research and exploration and in

SOV/4941

COVERAGE: The collection includes articles dealing with the present state of the petroleum industry, the scientific research problems in petroleum chemistry, the chemistry of petroleum, the composition of petroleum and petroleum products, the scientific principles of refining petroleum into motor fuels and lubricants, and the manufacture of synthetic products from hydrocarbon gases and petroleum. One article discusses the effect of chemical composition and additives on fuel combustion in jet engines. The material was presented at the Inter-University Conference on Petroleum Chemistry, held at the Moscow State University imeni M. V. Lomonosov November 26-28, 1956. No personalities are mentioned. References accompany most of the articles.

TABLE OF CONTENTS: None given

The authors and the titles of articles are as follows:

AUTHORS: Bogomolov, A.I., and Panina, K.I.

TITLE: A low-temperature catalytic transformation over natural clay of low-molecular-weight naphthene hydrocarbons of petroleum

PERIODICAL: Zhurnal prikladnoy khimii, v. 33, no. 12, 1960,
2757 ~ 2762

TEXT: Although catalytic changes and cracking of various hydrocarbons over artificial and natural aluminosilicates at the high temperature range, 450-500°C, have been extensively studied, catalytic reaction at lower temperatures have only recently been studied. At low temperatures, with prolonged thermal and contact effect of clays, the reactions to some extent follow a different pattern to that of ordinary cracking. A heavy fraction of petroleum, of b.p. range 500-550°C from which aromatic hydrocarbons were practically absent, consisting in the main of high molecular weight polycyclic

hydrocarbons and iso-substituted methanes, was used. As catalyst, natural clay was used both in an acid-activated form and in a non-activated state. The clay was compressed into tablets for use. Proportions by wt. of clay: oil were 5:1 (activated) and 10:1 (non-activated). The contact transformation of the oil was carried out under atmospheric pressure at a temperature of 150°C with heating for 8 hours. The clay, after the experiment was finished, was extracted with petroleum ether (b.p. up to 60°C) and with an alcohol-benzol mixture, the former extracting practically all the hydrocarbon content of the reaction product together with unreacted initial oil and the latter dissolving out the resins formed. The reaction products contained 93.4 % liquid hydrocarbons, 4.2 % resins and 1.4 % high-hydrocarbon residue in the clay. About 50 % of the initial oil was converted into lighter hydrocarbons with activated clay, the benzine and kerosene fraction formed were 25.6 % and with non-activated clay, 17.8 %, consisting mainly of methane, olefines and naphthene hydrocarbons. The reaction mechanism, in the first stage, is considered to be due to cyclic scission and break-
